

AI Usage

Tool: Microsoft Copilot

Part C - AI as a tutor

Prompt: "Work like a Python tutor. Explain this code. Identify three limitations. Suggest improvements. Don't rewrite the entire application. And ask me two questions."

AI response: It first explained the code. Then it identified three limitations: only the patient name is validated, time is stored as plain text, and there is no double-booking check. It then asked me two questions: what will happen if the time of an appointment is None, and how I would prevent the same practitioner from being booked twice at the same time.

My use: I checked the None time case by testing it, and it was accepted.

Part D - AI alternative

Prompt: "Write a simple beginner-friendly Python function that stores a patient's name, their practitioner's name, and appointment time. Don't use a database or GUI."

AI result: The AI produced ai_version.py (it validates all three fields). I did not copy it into my own file because it makes assumptions that have not been confirmed by the client.

Verification

I ran both versions with normal, blank, None and duplicate entries (verify_behaviour.py, test_stage01.py). The results are in comparison.md.

Declaration

The AI helped me review and compare code. I ran all of the code and can explain it.
