

Comparison

Question	Human Version	AI Version
Easy to understand?	Yes. It is short, written step by step and it was written by me. Some repetition in Section 1.	Yes, but more advanced: a loop over (label, value) pairs and is instance are more difficult to follow for a beginner than my plain if.
Runs successfully?	Yes. Prints appointments twice (Section 1 and Section 2) without any errors.	Yes. Stores and returns one appointment; all test cases behave as expected.
Uses only required features?	Mostly. List, dictionary, two functions. Nothing extra.	Mostly, but it includes .strip() cleaning, a return value and type checking that nobody asked for.
Adds assumptions?	Presumes that only the patient name is required and that time is any text.	Presumes that all three fields are required text, names should be trimmed, and a non-string is invalid. Did not ask the client.
Handles errors?	Partly. Patient name rejected (after Part G): Blank, None and spaces-only. Blank practitioner and no time is acceptable.	Better. If any of the three fields is blank or None, it is rejected with a clear message. Both versions prevent double booking.
Could I explain it?	Yes	Yes, after reading it, but I would need to find out what is instance and the tuple loop first.
